Candidate Serological Biomarkers for Cancer Identified from the Secretomes of 23 Cancer Cell Lines and the Human Protein Atlas*[S]

Chih-Ching Wu‡§, Chia-Wei Hsu§¶, Chi-De Chen¶, Chia-Jung Yu‡¶‖, Kai-Ping Chang**, Dar-In Tai‡‡, Hao-Ping Liu‡, Wen-Hui Su‡, Yu-Sun Chang‡¶, and Jau-Song Yu‡¶‖§§

Although cancer cell secretome profiling is a promising strategy used to identify potential body fluid-accessible cancer biomarkers, questions remain regarding the depth to which the cancer cell secretome can be mined and the efficiency with which researchers can select useful candidates from the growing list of identified proteins. Therefore, we analyzed the secretomes of 23 human cancer cell lines derived from 11 cancer types using one-dimensional SDS-PAGE and nano-LC-MS/MS performed on an LTQ-Orbitrap mass spectrometer to generate a more comprehensive cancer cell secretome. A total of 31,180 proteins was detected, accounting for 4,584 non-redundant proteins, with an average of 1,300 proteins identified per cell line. Using protein secretion-predictive algorithms, 55.8% of the proteins appeared to be released or shed from cells. The identified proteins were selected as potential marker candidates according to three strategies: (i) proteins apparently secreted by one cancer type but not by others (cancer type-specific marker candidates), (ii) proteins released by most cancer cell lines (pan-cancer marker candidates), and (iii) proteins putatively linked to cancer-relevant pathways. We then examined protein expression profiles in the Human Protein Atlas to identify biomarker candidates that were simultaneously detected in the secretomes and highly expressed in cancer tissues. This analysis yielded 6–137 marker candidates selective for each tumor type and 94 potential pan-cancer markers. Among these, we selectively validated monocyte differentiation antigen CD14 (for liver cancer), stromal cell-derived factor 1 (for lung cancer), and cathepsin L1 and interferon-induced 17-kDa protein (for nasopharyngeal carcinoma) as potential serological cancer markers. In summary, the proteins identified from the secretomes of 23 cancer cell lines and the Human Protein Atlas represent a focused reservoir of potential cancer biomarkers. ***Molecular & Cellular Proteomics 9:1100–1117, 2010.***

Cancer is a major cause of mortality worldwide, accounting for 10 million new cases and more than 6 million deaths per year. In developing countries, cancer is the second most common cause of death, accounting for 23–25% of the overall mortality rate (1). Notwithstanding improvements in diagnostic imaging technologies and medical treatments, the long term survival of most cancer patients is poor. Cancer therapy is often challenging because the majority of cancers are initially diagnosed in their advanced stages. For example, the 5-year survival rate for patients with HNC[1] is less than 50%. More than 50% of all HNC patients have advanced disease at the time of diagnosis (2, 3). Enormous effort has been devoted to screening and characterizing cancer markers for the early detection of cancer. Thus far, these markers include carcinoembryonic antigen, prostate-specific antigen, α-fetoprotein, CA 125, CA 15-3, and CA 19-9. Unfortunately, most biomarkers have limited specificity, sensitivity, or both (4). Thus, there is a growing consensus that marker panels, which are more sensitive and specific than individual markers, would increase the efficacy and accuracy of early stage cancer detection (4–8). The development of novel and useful biomarker panels is therefore an urgent need in the field of cancer management.

Proteomics technology platforms are promising tools for the discovery of new cancer biomarkers (9). Over the past decade, serum and plasma have been the major targets of proteomics studies aimed at identifying potential cancer biomarkers (10–13). However, the progress of these studies has been hampered by the complex nature of serum/plasma samples and the large dynamic range between the concentrations of different proteins (14). As cancer biomarkers are likely to be

[1] The abbreviations used are: HNC, head and neck cancer; BIGH3, transforming growth factor-β-induced protein ig-h3; CRC, colorectal carcinoma; emPAI, exponentially modified protein abundance index; GeLC-MS/MS, one-dimensional SDS-PAGE in conjunction with nano-LC-MS/MS; GO, gene ontology; HCC, hepatocellular carcinoma; HPA, Human Protein Atlas; IPI, International Protein Index; NPC, nasopharyngeal carcinoma; PAI-1, plasminogen activator inhibitor 1; TMHMM, transmembrane hidden Markov model; TPP, Trans-Proteomic Pipeline; FDR, false discovery rate; IHC, immunohistochemical; Mac-2BP, Mac-2-binding protein; ALCAM, activated leukocyte cell adhesion; MIF, macrophage migration inhibitory factor; TARC, thymus and activation-regulated chemokine.

present in low amounts in blood samples, the direct isolation of these markers from plasma and serum samples requires a labor-intensive process involving the depletion of abundant proteins and extensive protein fractionation prior to mass spectrometric analysis (15–18). Alternatively, the secretome, or group of proteins secreted by cancer cells (19), can be analyzed to identify circulating molecules present at elevated levels in serum or plasma samples from cancer patients. These proteins have the potential to act as cancer-derived marker candidates, which are distinct from host-responsive marker candidates. We, along with other groups, have demonstrated the efficacy of secretome-based strategies in a variety of cancer types, including NPC (20), breast cancer (21, 22), lung cancer (23, 24), CRC (25, 26), oral cancer (27), prostate cancer (28, 29), ovarian cancer (30), and Hodgkin lymphoma (31). In these studies, proteins secreted from cancer cells into serum-free media were resolved by one- or two-dimensional gels followed by in-gel tryptic digestion and analysis via MALDI-TOF MS or LC-MS/MS. Alternatively, the proteins were trypsin-digested in solution and analyzed by LC-MS/MS. In general, more proteins were detected in the secretome using the LC-MS/MS method than the MALDI-TOF MS method. Advanced protein separation and identification technologies have made it possible to detect more proteins in the secretomes of cancer cells, thereby facilitating the discovery of cancer biomarkers.

Although the cancer cell secretomes of various tumor types have been individually analyzed by different groups using distinct protocols, few studies have used the same protocol to compare cancer cell secretomes derived from different tumor types. We previously assessed the secretomes of 21 cancer cell lines derived from 12 cancer types (*i.e.* consisting of 795 protein identities and 325 non-redundant proteins) by one-dimensional gel and MALDI-TOF MS (25). Our preliminary findings revealed that different cell lines have distinct secreted protein profiles and that several putative biomarkers, such as Mac-2BP (20, 26, 27, 29) and cathepsin D (21, 23, 32), present in the secretome of a given cancer cell type are commonly shared among different cancers. These observations suggest that an in-depth comparison of secretomes derived from different tumor types may identify marker candidates common to most cancers as well as markers for specific cancer types. As an increasing number of proteins are identified in the secretomes of various cancer cell lines, scientists are faced with the challenge of quickly and efficiently narrowing down the list to candidates with higher chances of success during validation testing with precious clinical specimens.

In the present study, we applied one-dimensional SDS-PAGE in conjunction with nano-LC-MS/MS (GeLC-MS/MS) (33, 34) to analyze the conditioned media of 23 cancer cell lines derived from 11 cancer types, including NPC, breast cancer, bladder cancer, cervical cancer, CRC, epidermoid carcinoma, liver cancer, lung cancer, T cell lymphoma, oral cancer, and pancreatic cancer. Within this data set, 4,584 non-redundant proteins were identified from a total of 23 cell lines, yielding an average of ~1,300 proteins per cell line. Potential marker candidates were identified via the comparative analysis of different cell line secretomes and by putative linkages to cancer-relevant pathways. The selected proteins were further compared with the HPA (35) to generate a focused data set of proteins that are secreted or released, cancer type-specific, and highly expressed in human cancer tissues. Finally, we selectively validated four proteins as potential serological cancer markers using blood samples from cancer patients.

EXPERIMENTAL PROCEDURES

Cell Culture—Colorectal carcinoma cells (Colo205, ATCC CCL-222; SW480, ATCC CCL-228; and SW620, ATCC CCL-227), acute T cell leukemia cells (Jurkat, ATCC TIB-152), bladder cancer cells (U1 and U4), oral cancer cells (OEC-M1; SCC-4, ATCC CRL-1624), and lung cancer cells (CL_{1-0} and CL_{1-5}) were maintained in RPMI 1640 medium with 10% fetal bovine serum and antibiotics at 37 °C in an atmosphere of 5% CO_2. Nasopharyngeal carcinoma cells (NPC-TW02, NPC-TW04, and NPC-BM1), HCC cells (SK-Hep-1, ATCC HTB-52; Hep G2, ATCC HB-8065; and Hep 3B, ATCC HB-8064), cervical carcinoma cells (C-33A, ATCC HTB-31), HeLa cells (ATCC CCL-2), epidermoid carcinoma cells (A431, ATCC CRL-1555), pancreatic carcinoma cells (PANC-1, ATCC CRL-1469; MIA PaCa-2, ATCC CRL-1420), and breast cancer cells (MCF-7, ATCC HTB-22; and MDA-MB435S, ATCC HTB-129) were grown in Dulbecco's modified Eagle's medium with 10% fetal bovine serum and antibiotics at 37 °C in an atmosphere of 5% CO_2. All cell culture reagents were obtained from Invitrogen. The NPC-TW02 and NPC-TW04 cell lines were kindly provided by Dr. C.-T. Lin (Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan). The NPC-BM1 cell line was obtained from Dr. S.-K. Liao (Graduate Institute of Clinical Medicine, Chang Gung University, Tao-Yuan, Taiwan). The CL_{1-0} and CL_{1-5} cell lines were kindly provided by Dr. P.-C. Yang (Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan). The U1 and U4 cells were obtained from Dr. Y.-M. Yung (Department of Physiology and Pharmacology, Chang Gung University, Tao-Yuan, Taiwan).

Preparation of Conditioned Media and Cell Extracts—Conditioned media from the various cancer cell lines were collected and processed as described previously (25). Briefly, cancer cells were grown to confluence in 15-cm tissue culture dishes. The cells were washed with serum-free media and incubated in serum-free media for 24 h. The supernatants were then harvested and centrifuged to remove the intact cells followed by centrifugation in Amicon Ultra-15 tubes (molecular mass cutoff, 5,000 Da; Millipore, Billerica, MA) to concentrate and desalt the supernatants. Cells remaining on the dishes were washed twice with PBS and lysed in hypotonic buffer (10 mM Tris, pH 7.4, 1 mM EDTA, 1 mM EGTA, 50 mM NaCl, 50 mM NaF, 20 mM $Na_4P_2O_7$, 1 mM Na_3VO_4, 1 mM PMSF, 1 mM benzamidine, 0.5 μg/ml leupeptin, and 1% Triton X-100) on ice for 15 min. The cell lysates were collected, sonicated on ice, and centrifuged at 10,000 $\times$ *g* for 25 min at 4 °C. The resulting supernatants were used as cell extracts (20). The protein concentrations of the various samples were determined using the BCA protein assay reagent from Pierce.

One-dimensional SDS-PAGE and In-gel Protein Digestion—In preparation for secretome analyses, proteins (50 μg) were applied to 8–14% gradient gels for SDS-PAGE. After staining by 0.5% Coomassie Brilliant Blue G-250 (AppliChem GmbH, Darmstadt, Germany), the gel lane was cut into 70 pieces and subjected to in-gel tryptic digestion as described by Wu *et al.* (25). Briefly, the gel pieces were

destained in 10% methanol (Mallinckrodt Baker), dehydrated in acetonitrile (Mallinckrodt Baker), and dried using a SpeedVac. The proteins were reduced with 25 mM NH_4HCO_3 containing 10 mM dithiothreitol (Biosynth AG) at 60 °C for 30 min and alkylated with 55 mM iodoacetamide (Amersham Biosciences) at room temperature for 30 min. After reduction and alkylation, proteins were digested via overnight incubation with sequencing grade modified porcine trypsin (20 μg/ml) (Promega, Madison, WI) at 37 °C. Peptides were extracted using acetonitrile and dried in a SpeedVac.

Reverse-phase Liquid Chromatography/Tandem Mass Spectrometry—To analyze the cancer cell secretomes, each peptide mixture was reconstituted in HPLC buffer A (0.1% formic acid; Sigma), loaded across a trap column (Zorbax 300SB-C18, 0.3 × 5 mm; Agilent Technologies, Wilmington, DE) at a flow rate of 0.2 μl/min in HPLC buffer A, and separated on a resolving 10-cm analytical C_{18} column (inner diameter, 75 μm) using a 15-μm tip (New Objective, Woburn, MA). The peptides were eluted using a linear gradient of 0–10% HPLC buffer B (*i.e.* 99.9% ACN containing 0.1% formic acid) for 3 min, 10–30% buffer B for 35 min, 30–35% buffer B for 4 min, 35–50% buffer B for 1 min, 50–95% buffer B for 1 min, and 95% buffer B for 8 min with a flow rate of 0.25 μl/min across the analytical column.

The LC apparatus was coupled with a two-dimensional linear ion trap mass spectrometer (LTQ-Orbitrap, Thermo Fisher, San Jose, CA), which was operated using Xcalibur 2.0 software (Thermo Fisher). Intact peptides were detected in the Orbitrap at a resolution of 30,000. Internal calibration was performed using the ion signal of $(Si(CH_3)_2O)_6H^+$ at *m/z* 445.120025 as a lock mass (36). We used a data-dependent procedure that alternated between one MS scan and six MS/MS scans for the six most abundant precursor ions in the MS survey scan. The *m/z* values selected for MS/MS were dynamically excluded for 180 s. The electrospray voltage applied was 1.8 kV. Both MS and MS/MS spectra were acquired using the one microscan with a maximum fill time of 1,000 and 100 ms for MS and MS/MS analyses, respectively. Automatic gain control was used to prevent overfilling of the ion trap, and 5×10^4 ions were accumulated in the ion trap for the generation of MS/MS spectra. The *m/z* scan range for MS scans was 350–2,000 Da.

Bioinformatics—The resulting MS/MS spectra were used to search the non-redundant IPI human sequence database Version 3.26 (released February 2007; 67,665 sequences; 28,353,548 residues) of the European Bioinformatics Institute using the SEQUEST algorithm (Thermo Fisher). Up to two missed cleavages were allowed, and searches were performed with variable oxidation of methionine residues (16 Da) and fixed modification for carbamidomethylcysteines (57 Da). A fragment ion mass tolerance of 0.5 Da and a parent ion mass tolerance of 10 ppm were used for the search engine with trypsin as the digestion enzyme. The random sequence database was used to estimate false-positive rates for peptide matches, and the false-positive rate for the peptide sequence matches using the criteria was estimated to be <1% via random database searching.

Protein identities were validated using the open source TPP software (Version 3.3). The SEQUEST search resulted in a DTA file. The raw data and DTA files containing information about identified peptides were then processed and analyzed in the TPP. The TPP software includes a peptide probability score program, PeptideProphet, that aids in the assignment of peptide MS spectra (37), as well as a ProteinProphet program that assigns and groups peptides to a unique protein or a protein family if the peptide is shared among several isoforms (38). ProteinProphet allows for the filtering of large scale data sets with assessment of predictable sensitivity and false-positive identification error rates. We used PeptideProphet and ProteinProphet probability scores ≥0.95 to ensure an overall false-positive rate below 0.5%. Furthermore, proteins with single peptide identities were excluded from this study. Information about the PeptideProphet and ProteinProphet programs can be obtained from the Seattle Proteome Center at Institute for Systems Biology.

We used the SignalP program with hidden Markov models to predict the presence of secretory signal peptide sequences (39, 40). In addition, we used the SecretomeP program to predict non-signal peptide-triggered protein secretion (41) and the TMHMM to predict transmembrane helices in proteins (42). The identified proteins were further analyzed using ProteinCenter (Proxeon Bioinformatics, Odense, Denmark), a proteomics data mining and management software, to compare cell line secretomes with each other, functionally categorize the identified proteins, and calculate the emPAI (43, 44).

Hierarchical Clustering—The emPAI values of identified proteins were imported into Microsoft Excel. If a protein was identified in one cell line but not the other, half the minimum emPAI value from the data set was assigned to that protein to facilitate visualization and comparison. All values were then transformed to *Z* scores, a commonly used normalization method for microarray data (45). The *Z* scores were calculated as $Z = (X - \mu_x)/\sigma_x$ where *X* is the individual emPAI value, μ_x is the mean of emPAI values for a identified protein across cell lines, and σ_x is the standard deviation associated with μ_x. A spreadsheet containing the *Z* scores was uploaded to the Partek® Genome Suite (Partek Inc., St. Louis, MO) and analyzed using a two-way hierarchical clustering algorithm according to Pearson distance and Ward's aggregation method. Cell lines and proteins were organized into mock phylogenetic trees (dendrograms) with the cell lines shown along the *x* axis and the proteins along the *y* axis.

Network Analysis—Proteins selected from the clustering analysis were converted into gene symbols and uploaded into MetaCore (GeneGo, St. Joseph, MI) for biological network building. MetaCore consists of curated protein interaction networks based on manually annotated and regularly updated databases. The databases describe millions of relationships between proteins according to publications on proteins and small molecules. The relationships include direct protein interactions, transcriptional regulation, binding, enzyme-substrate interactions, and other structural or functional relationships. The "shortest paths" and "analyze network" algorithms were used to map the hypothetical networks of uploaded proteins. The relevant pathway maps were then prioritized based on their statistical significance with respect to the uploaded data sets.

Patient Population and Clinical Specimens—Plasma samples were collected from 45 healthy controls (*i.e.* 32 men and 13 women ranging in age from 43 to 77 years; mean, 62.2 years), 44 patients with liver cancer (*i.e.* 32 men and 13 women ranging in age from 44 to 77 years; mean, 63.4 years), and 44 patients with lung cancer (*i.e.* 28 men and 16 women ranging in age from 32 to 88 years; mean, 64.7 years). Serum samples were collected from 45 healthy controls (*i.e.* 26 men and 19 women ranging in age from 21 to 72 years; mean, 48.2 years) and 45 NPC patients (*i.e.* 32 men and 13 women ranging in age from 16 to 79 years; mean, 47.2 years). All the blood samples were collected at Chang Gung Memorial Hospital. The study protocol was approved by the Medical Ethics and Human Clinical Trial Committee at Chang Gung Memorial Hospital. All patients entered in the study signed an informed consent.

Blood samples were collected from the patients preoperatively following a standardized protocol. Plasma and serum samples were prepared by collecting blood in EDTA and empty tubes, respectively, and left at room temperature (for a maximum of 30 min) until centrifugation. Plasma samples were centrifuged at 2,000 × *g* for 10 min at room temperature to pellet the cells. Serum samples were centrifuged at 1,500 × *g* for 10 min at 4 °C. After centrifugation, samples were divided into 1.0-ml aliquots in sterile cryotubes and immediately frozen at −80 °C for storage until ELISAs. The samples had only undergone one freeze/thaw cycle before the measurements were conducted.

Western Blot Analysis—The prepared samples (20 μg of protein) were separated by SDS-PAGE, transferred to PVDF membranes (Millipore), and probed with various antibodies (*i.e.* anti-fascin, anti-BIGH3, anti-PAI-1 (Santa Cruz Biotechnology), and anti-β-tubulin (MDbio, Taipei, Taiwan)) as described previously (20, 27). Polyclonal antibodies specific to prosaposin were produced in rabbits using recombinant proteins, and these antibodies were affinity-purified as described in the supplemental Materials and Methods. Proteins of interest were detected with alkaline phosphatase-conjugated goat anti-rabbit IgG antibodies (Santa Cruz Biotechnology) and visualized using the CDP-Star™ chemiluminescent substrate (Roche Applied Science) according to the manufacturer's protocol.

ELISA—The concentrations of four candidate proteins were measured by ELISA in the blood samples of healthy controls and cancer patients. The concentrations of CD14 (ELISA kit from R&D Systems, Minneapolis, MN), stromal cell-derived factor 1 (SDF-1) (ELISA kit from R&D Systems), and cathepsin L1 (ELISA kit from Bender MedSystems) were measured according to their respective manufacturer's instructions. An ELISA developed in house was used to measure ISG15 as described in the supplemental Materials and Methods.

Statistical Analysis—For the analysis of ELISA results, continuous measures were summarized using means, standard deviations, medians, and interquartile ranges. Differences between controls and cancer patients in blood concentrations of CD14, SDF-1, cathepsin L1, and ISG15 were performed using the nonparametric Mann-Whitney *U* test. Statistical analyses were conducted using SPSS software (Version 13.0, SPSS Inc., Chicago, IL). Two-tailed *p* values of 0.05 or less were considered significant.

RESULTS

Secretomes of 23 Cancer Cell Lines—We previously examined the secretomes of 21 cancer cell lines using one-dimensional SDS gels and MALDI-TOF MS and identified an average of 38 secreted proteins in each cell line (25). More recently, we identified 1,096 and 1,830 proteins in the secretomes of two lung cancer cell lines (CL_{1-0} and CL_{1-5}, respectively) using the GeLC-MS/MS strategy (46). To facilitate the secretome-based discovery of cancer biomarkers, we have now used the GeLC-MS/MS strategy to perform an in-depth analysis of conditioned media from 21 cancer cell lines derived from 10 cancer types, including NPC (NPC-TW02, NPC-TW04, and NPC-BM1), colon cancer (Colo205, SW480, and SW620), HCC (SK-Hep-1, Hep G2, and Hep 3B), oral cancer (OEC-M1 and SCC-4), bladder cancer (U1 and U4), breast cancer (MCF7 and MDA-MB-435S), cervical cancer (C-33A and HeLa), pancreatic cancer (PANC-1 and MIA-PaCa-2), epidermoid carcinoma (A431), and T cell lymphoma (Jurkat). A schematic diagram of the procedure is shown in Fig. 1. Proteins (50 μg) in the conditioned media collected from cells cultured in serum-free media for 24 h were resolved by SDS-PAGE, visualized by Coomassie Blue staining, consecutively sliced into 70 pieces, digested individually with trypsin, and analyzed by LC-ESI-MS/MS on an LTQ-Orbitrap MS. The protein patterns observed in conditioned media from 21 cancer cell lines and two lung cancer cell lines are shown in Fig. 2*A*. As a quality control, we performed Western blot to examine the distribution of β-tubulin, an abundant cytosolic protein, between the total cell lysates and conditioned media.

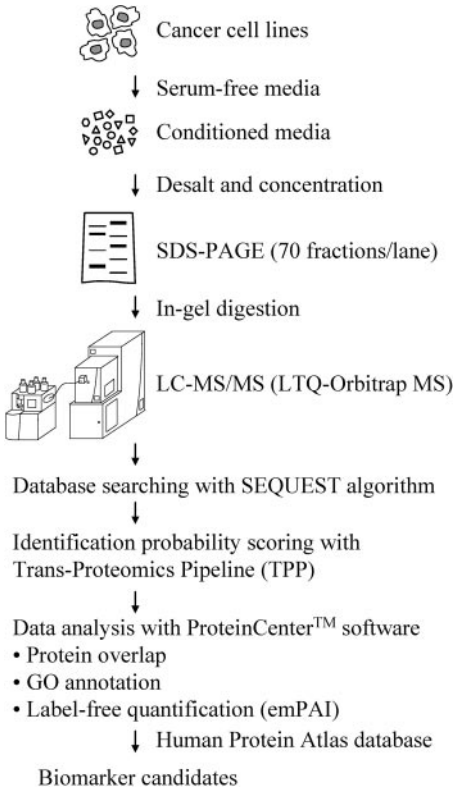

FIG. 1. **Cancer cell secretome profiling via analysis of conditioned media from cancer cell lines.** The strategy involves the proteomic profiling of cancer cell-conditioned media, secretome analysis, and subsequent preliminary validation using the HPA.

β-Tubulin was clearly detected in the total cell extracts but not in the conditioned media (Fig. 2*B*). We also found that serum starvation for 24 h had little effect on cell viability compared with cells cultured in the presence of 10% serum (supplemental Fig. 1). These observations collectively indicate that recovery of proteins in the conditioned media was not due to cell death.

The resulting MS/MS spectra were used in a search of the non-redundant IPI human sequence database (Version 3.26) using the SEQUEST algorithm. The search results were analyzed using the open source TPP software (Version 3.3) with stringent criteria regarding peptide probability (≥0.95) and protein probability (≥0.95) (38). Proteins present in the two lung cancer cell lines (46) as well as proteins identified by this analysis are summarized in Table I. Emphasis was placed on proteins identified by multiple (*i.e.* at least two) peptides because the chances of false-positive results decrease exponentially with each additional peptide identified (47). After setting the cutoffs, an average of 1,356 proteins per cell line were examined, and a total of 31,180 protein identities, accounting for 4,584 non-redundant proteins, were detected (Table I and supplemental Table 1). In addition to identifying proteins in each cancer cell secretome, we applied the emPAI (43) to estimate the abundance of each protein in the secretome of each cell line (supplemental Table 1). The false dis-

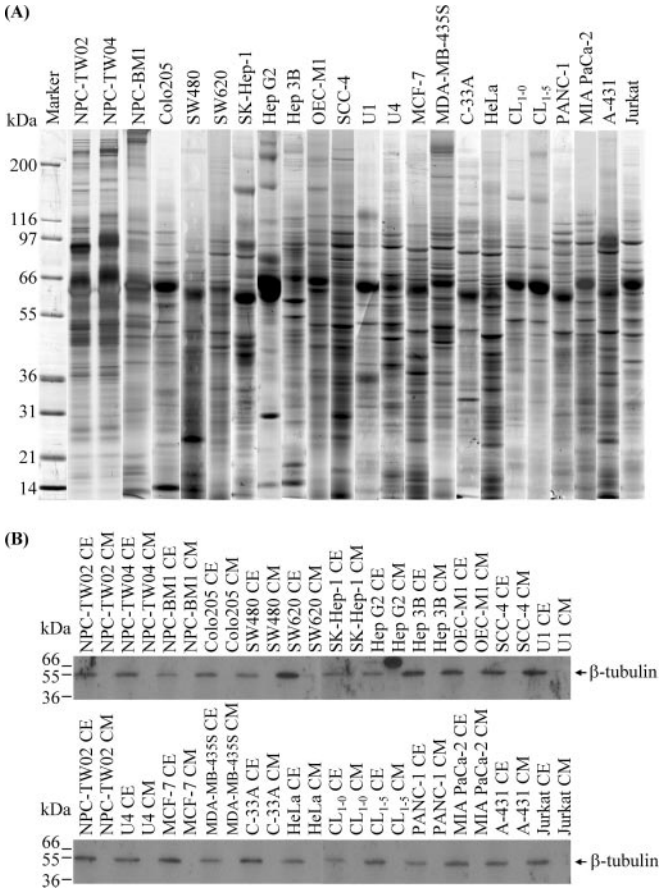

FIG. 2. **SDS-PAGE analysis of conditioned media harvested from cancer cells.** *A*, conditioned media from cancer cells were collected and processed as described under "Experimental Procedures." Proteins (50 μg) were resolved on 8–14% gradient SDS gels and stained with Coomassie Blue. Protein bands were excised for further analysis. *B*, proteins (40 μg) in the conditioned media (*CM*) and cell extracts (*CE*) were analyzed via Western blotting using an anti-β-tubulin antibody.

covery rate (FDR) of peptide detection was empirically determined by searching the data set against a random IPI Human database (Version 3.26) using the same search parameters and TPP cutoffs. The FDRs determined for each cell line are shown in Table I; all were <1%.

Distribution and Ontology Analysis of Identified Proteins—The identified proteins were further analyzed using bioinformatics programs designed to predict protein secretion pathways (Table II and supplemental Table 2). Among the 4,584 non-redundant proteins identified, the SignalP program predicted that 998 proteins were secreted in the classical secretory pathway (*i.e.* the endoplasmic reticulum/Golgi-dependent pathway; SignalP probability ≥0.90) based on the presence of a signal peptide (39, 40). The SecretomeP program predicted that 1,438 proteins were released via the nonclassical secretory pathway (SignalP probability <0.90 and SecretomeP score ≥0.50) (41). In addition, the TMHMM determined that 121 integral membrane proteins were not secreted via the classical or nonclassical secretion pathways (42). The predicted secretion pathways of the proteins in each cell line are summarized in Table II and supplemental Table 1. Collectively, these analyses predicted that 55.8% (2,557 of 4,584) of the identified proteins were released into the conditioned media of cultured cancer cells via different mechanisms. It should be noted that many chemokines, cytokines, and growth factors, which are known as very low abundance secreted proteins, could be detected in the secretomes of various cancer cell lines (supplemental Table 3), thereby demonstrating the sensitivity of the GeLC-MS/MS strategy. To evaluate the effectiveness of this protocol with regard to secretome analysis, we analyzed proteins extracted from lysates of NPC-TW04 and A431 cells that remained on culture dishes after the removal of conditioned media. The results

[a] Proteins predicted by the SignalP program to be secreted via the classical secretion pathway (SignalP probability $\geq$0.90).
[b] Proteins predicted to be secreted by the nonclassical secretion pathway using SignalP and SecretomeP (SignalP probability $<$0.90 and SecretomeP score $\geq$0.50).
[c] Proteins predicted by the TMHMM to form integral membrane proteins that were not predicted to be secreted via the classical or nonclassical secretion pathways.
[d] Proteins that could not be classified as classical secreted, nonclassical secreted, or integral membrane proteins.

showed that only 34.0% (415 of 1,219) and 33.8% (395 of 1,169) of the proteins in NPC-TW04 and A431 cells, respectively, were predicted to be secreted (data not shown). Of the 4,584 proteins identified in this report, 1,241 (27.1%) were found in the Human Plasma Proteome Project database (48) (supplemental Table 2).

ProteinCenter software was used to predict the functions of the 4,584 identified proteins based on universal GO annotation terms. These proteins were linked to at least one annotation term within the GO molecular function and biological process categories, respectively. As shown in Fig. 3*A*, the top three most common molecular functions were protein binding (63.4%), catalytic activity (61.3%), and metal ion binding (30.6%). The major biological process categories included metabolic processes (73.8%) and regulation of biological processes (34.5%) followed by cell organization (33.7%) and cell communication (26.8%) (Fig. 3*B*). The results of our GO analysis of identified proteins in the molecular function and biological process categories are shown in supplemental Tables 4 and 5, respectively.

Overlap of Identified Proteins between All Cell Lines Examined—The proteins identified among the 23 cell lines were analyzed for overlapping members (Table III and supplemental Table 2). One hundred and seventy-two proteins (3.8% of the 4,584 proteins) were detected in all cancer cell secretomes. About 23.0% of the 4,584 proteins were detected in more than half ($\geq$12) of the cell lines, and 35.1% were found in 3–11 cell lines. Nearly one-third (*i.e.* 29.3%) of the 4,584 proteins were uniquely detected in the secretome of one of the 23 cell lines, and 12.6% (576 proteins) were identified in two of the 23 cell lines.

To reduce the number of potential tumor marker candidates, we combined proteins identified in the secretomes of cell lines from each cancer type to form a list of non-redundant proteins for each cancer type. These 11 lists were used to assess the overlap in identified proteins (Table IV and supplemental Table 6). A significant portion (36.3%) of the proteins were found in more than half (at least six) of the cancer types; 33.6% (1,539 proteins) were detected in two to five cancer types, and 30.1% (1,381 proteins) were detected in a single cancer type. Taken together, these data reveal that cell lines from different tumor origins secrete/release hundreds of common proteins and that cancer cell lines can also secrete/release proteins unique to a specific cancer type.

Evaluation of Potential Cancer-specific Biomarkers—Detection of proteins that are uniquely released by each cancer type might facilitate the discovery of biomarkers for individual cancers. Thus, we focused our attention on the 1,381 proteins that were uniquely detected in the secretomes of a specific

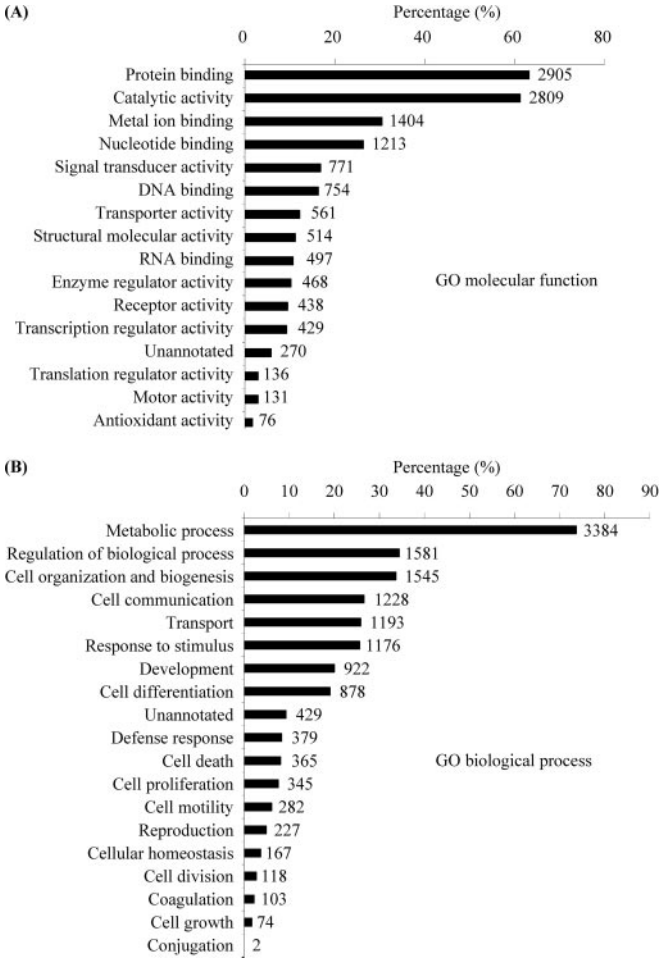

FIG. 3. **Functional classification of proteins identified in conditioned media using ProteinCenter software based on universal GO annotation terms.** The proteins were linked to at least one annotation term within the GO molecular function (*A*) and biological process (*B*) categories. The *numbers* represent the proteins annotated as each GO term.

cancer type. To efficiently narrow down our candidate list of potential cancer-specific biomarkers, we consulted the HPA. This database contains the immunohistochemical (IHC) staining profiles of numerous proteins in a variety of cancerous and non-cancerous tissues based on more than 8,800 antibodies (35). We searched all 1,381 proteins in the HPA database and selected those whose expression has been examined in corresponding cancer tissues from a small number of patients. The IHC staining profiles of corresponding non-cancer tissues in the HPA were also analyzed, although only three or fewer than three biopsies were available (supplemental Table 7). We found that 603 of 1,381 proteins have been examined in their corresponding tumor tissues (Table V). Among these, 77.8% (469) of the proteins were detected in more than 50% of the tumor tissue sections (Table V). The IHC staining results for the 603 proteins and their corresponding cancer types from the HPA database are summarized in Table V and supplemental Table 7.

TABLE III
Proteins detected in secretomes of 23 cancer cell lines

[a] The average emPAI values of all identified proteins. The average emPAI value for each protein was determined by adding the emPAI values of each identified protein and dividing the sum by the number of cell lines in which the protein was detected. The average emPAI value shown here was determined by adding the average emPAI values of each protein and dividing the sum by the protein numbers.

TABLE IV
Proteins detected in secretomes of cell lines derived from 11 cancer types

Detected no. of cancer types	No. of proteins	%
11	599	13.1
10	267	5.8

1	1,381	30.1

The following examples illustrate the ability of our analyses to identify multiple marker candidates that warrant further validation (Table VI). Among the 40 proteins detected in most CRC tissues (Table V), cell surface A33 antigen was found to be mainly negative in other cancer types, whereas neutral amino acid transporter A, isoform CSBP1 of mitogen-activated protein kinase 14, and bone morphogenetic protein 4 were overexpressed in CRC relative to other cancers. Among

the 70 proteins positively stained in most HCC tissues (Table V), bile salt sulfotransferase, ornithine carbamoyltransferase, monocyte differentiation antigen CD14, and isoform 1 of asialoglycoprotein receptor 2 were less immunoreactive in tissues of other cancer types, whereas multidrug resistance protein 1 and vitamin K-dependent protein C were overexpressed in HCC *versus* other cancers. Compared with other cancers, bladder cancer tissues reacted more strongly with proteins such as cadherin-6, squalene synthetase, ribophorin II, and 15-hydroxyprostaglandin dehydrogenase. The levels of neurogenic locus notch homolog protein 3 and trefoil factor 1 were higher in breast cancer tissues *versus* tissues of other cancers. Compared with non-tumor lung tissues, stromal cell-derived factor 1 (CXCL12) reacted more strongly with lung cancer tissues.

Evaluation of Potential Pan-cancer Biomarkers—The identification of proteins that have a high frequency of detection in the conditioned media of different cell lines clearly revealed proteins commonly released by various cancer cells. A total of 172 proteins (3.8%) were found in the conditioned media of all

cell lines examined (Table III and supplemental Table 8). To evaluate the potential of these proteins to serve as pan-cancer marker candidates, we evaluated their expression in the tumor tissues of nine cancer types in the HPA database, including breast, cervix, colon, head and neck, liver, lung, pancreas, skin, and bladder cancers (35). In the HPA database (Version 5.0), 114 of the 172 proteins had been analyzed by IHC staining (supplemental Table 8). Among the proteins detected in more than half of the tumor tissue sections, 70.2% (80 of 114) of the proteins were observed in all nine tumor types, and 12.3% (14 of 114) of the proteins were detected in eight of nine cancer types (supplemental Table 8). Moreover, 45 proteins were detected in human plasma samples as documented in the Human Plasma Proteome Project (supplemental Table 8), and eight of 45 proteins showed negative or weak staining in over half of the nine corresponding normal tissue types (Table VII). These observations suggest that secreted proteins common to multiple cancer cell lines are potential pan-cancer markers.

Hierarchical Clustering Analysis for Pathway-based Biomarker Searches—A new approach toward biomarker discovery was recently proposed wherein pathways are monitored and targeted rather than individual proteins (49, 50). Many secreted proteins appear to play important roles in the cancer microenvironment (51); thus, we attempted to cluster proteins according to their abundance in the conditioned media from each cancer cell line in an effort to identify potential pathways involved in the regulation of cancer microenvironments. Toward this end, we calculated the emPAI values of all proteins identified in the conditioned media of 23 cell lines, transformed these values to *Z* scores, and analyzed these data via unsupervised hierarchical classification as described under "Experimental Procedures." To examine the ability of emPAI-based *Z* scores to calculate the relative abundance of proteins in the conditioned media, we compared the *Z* score values of four selected targets (*i.e.* BIGH3, fascin, PAI-1, and prosaposin) with their corresponding signal intensities as determined by Western blot analyses of conditioned media (supplemental Fig. 2). There was a significant correlation between emPAI-based *Z* scores and Western blot-based *Z* scores, suggesting that emPAI-based *Z* scores can be used to estimate the relative abundance of proteins in conditioned media.

When proteins detected in the conditioned media were clustered according to *Z* scores, the three NPC cell lines and the two lung cancer cell lines clustered together. However, the other cell lines could not be categorized by tissue type (Fig. 4*A* and supplemental Fig. 3). We further selected the 79 proteins with the most different features used to distinguish the NPC cell lines (Fig. 4*B* and supplemental Table 9).

We then used MetaCore software to build biological networks and analyze the possible biological linkages between these 79 proteins. When the shortest paths algorithm was used to map the shortest interaction path and obtain a global view, 36 proteins were brought together in the net-

works (supplemental Fig. 4). The networks shown in supplemental Fig. 4 demonstrate the enormous number of complex interactions between the 36 identified proteins and various intracellular signaling proteins. The 79 proteins were analyzed using the MetaCore analyze network algorithm to further explore their involvement in various biological processes. This analysis revealed a significant number of networks involved in cell adhesion and migration (Fig. 5*A*; $p = 2.5 \times 10^{-26}$) and immune system regulation (Fig. 5*B*; $p = 5.7 \times 10^{-22}$). The 24 proteins involved in both networks are listed in Table VIII. Among them, fibronectin is a potential NPC serum biomarker (20), laminin subunit γ-1 is overexpressed in NPC via the down-regulation of *mir-29c* microRNA (52), and cathepsin L is highly expressed in NPC, and its overexpression correlates with lymph node metastasis and distant metastasis (53). These observations support the feasibility of a pathway-based search strategy for biomarker discovery and furthermore suggest that the 22 additional proteins in the networks described above are potential NPC biomarkers that warrant further investigation.

Validation of Monocyte Differentiation Antigen CD14, Stromal Cell-derived Factor 1, Cathepsin L1, and Interferon-induced 17-kDa Protein as Potential Serological Cancer Biomarkers—To determine the clinical relevance of the results described above, we used ELISA to detect the levels of a potential liver cancer marker known as monocyte differentiation antigen CD14 (Table VI), a potential lung cancer marker known as SDF-1 (or CXCL12) (Table VI), and two potential NPC markers (*i.e.* cathepsin L1 and interferon-induced 17-kDa protein (ISG15)) (Table VIII) in serum or plasma samples from cancer patients and healthy controls. The CD14 and SDF-1 markers were selected based on a combined analysis of secretomes from 23 cell lines and the HPA, whereas cathepsin L1 and ISG15 were selected via the pathway-based strategy. In our data set, CD14 was selectively detected in the secretome of HepG2 cell line on the basis of three tryptic peptides (*i.e.* AFPALTSLDLSDNPGLGER, LTVGAAQVPAQLLVGALR, and TGTMPPLPLEATGLALSSLR). In the HPA database, expression of CD14 (detected using the HPA002127 antibody) was observed in different cell types in a variety of normal human tissues but not in bile duct cells or hepatocytes in normal liver tissue. Interestingly, positive CD14 staining was observed at a much higher rate (*i.e.* nine of 11 times) in HCC specimens than in the other 19 cancer types according to data obtained from the HPA database (supplemental Fig. 5). The SDF-1 marker was selectively detected in the CL_{1-5} secretome based on the presence of two tryptic peptides (FFESHVAR and ILNTPNCALQIVAR). In the HPA database, SDF-1 expression (detected using the CAB017564 antibody) was found in different cell types in a variety of normal human tissues, including macrophages in the lung, but was not found in lung alveolar cells. Positive staining of SDF-1 was observed in many cancer types, including seven of 10 lung cancer specimens, according to data obtained from the HPA database (supplemental Fig. 6). As shown in Fig. 6*A*, the plasma levels of CD14 were statistically higher in patients with liver cancer ($n = 44$) than in healthy controls ($n = 45$) (1.83 ± 0.36 and 1.43 ± 0.29 μg/ml, respectively; $p = 0.0117$). The SDF-1 plasma levels were significantly higher in patients with lung cancer ($n = 44$) than in healthy controls ($n = 44$) (4.01 ± 1.57 and 3.11 ± 0.56 ng/ml, respectively; $p = 0.0007$) (Fig. 6*B*). Finally, the serum levels of

[a] Networks were constructed using the analyze network algorithm in MetaCore.

cathepsin L1 (Fig. 6*C*) and ISG15 (Fig. 6*D*) were elevated in patients with NPC relative to healthy controls (6.87 $\pm$ 3.30 and 5.46 $\pm$ 1.36 ng/ml, respectively, for cathepsin L1; $p = 0.0106$; and 3.53 $\pm$ 3.91 and 1.90 $\pm$ 2.16 ng/ml, respectively, for ISG15; $p = 0.0184$).

DISCUSSION

Although much time and effort have been devoted to the study of molecular alterations in cancer, early detection remains one of the most promising approaches to reducing the growing cancer burden. Thus, biomarkers capable of early detection will play a key role in the management and control of most, if not all, cancers in the future (54, 55). Cancer biomarkers should be measurable in bodily fluids, especially in blood samples, to allow for the screening of large populations (11, 56). As numerous proteins have been found to exhibit altered levels in various cancer tissues, recent efforts have focused on compiling lists of general and cancer-specific cancer biomarker candidates, focusing on those with a higher chance of detection in bodily fluids (4, 57). Thus, the present study sought to conduct an in-depth analysis of the secretomes of 23 cancer cell lines and the HPA in an effort to construct a focused data set of serological cancer biomarker candidates.

Proteins detected in cancer cell secretomes include growth factors, proteases, cell motility factors, cytokines, chemokines, and/or cell surface receptors. These proteins play

FIG. 5. **Biological network analysis of NPC-related proteins.** The proteins in Fig. 4*B* were uploaded to the MetaCore mapping tool. The biological networks were generated using the analyze network algorithm. Two prominent networks involved in cell adhesion (*A*) and immune system regulation (*B*) were identified from the protein list. The *concentric circles* denote uploaded proteins. *Nodes* represent proteins with *shapes* representing functional class. *Lines between* the *nodes* indicate direct protein-protein interactions. *Green*, *red*, and *gray lines* represent stimulatory, inhibitory, or unspecified interactions, respectively. 90K, tumor-associated antigen 90K/Mac-2 binding protein; ACP1, low molecular weight phosphotyrosine protein phosphatase; APRIL/TNFSF13, a proliferation-inducing ligand/tumor necrosis factor ligand superfamily member 13; BPAG1/2, bullous pemphigoid antigen 1/2; CR1, complement component (3b/4b) receptor 1; CSF1, colony stimulating factor 1; DBL, dichaete beadex lethal; DNM1L/DRP1, dynamin 1-like protein/dynamin related protein 1; FAK1, focal adhesion kinase 1; FGF2, fibroblast growth factor 2; GA6S, galactosamine (N-acetyl)-6-sulfate sulfatase; ILK, integrin-linked protein kinase; IP-30, interferon, gamma-inducible protein 30; LAMA2/3/5, laminin subunit α-2/3/5; M-CSF, macrophage colony-stimulating factor; MMP-13, collagenase 3; PSMB4, proteasome subunit β type-4; RASGRF1, ras protein-specific guanine nucleotide-releasing factor 1; SLC3A2, solute carrier family 3, member 2; STAT1/5, signal transducer and activator of transcription 1/5; VEGFR3, vascular endothelial growth factor receptor 3; XIAP, X-linked inhibitor of apoptosis.

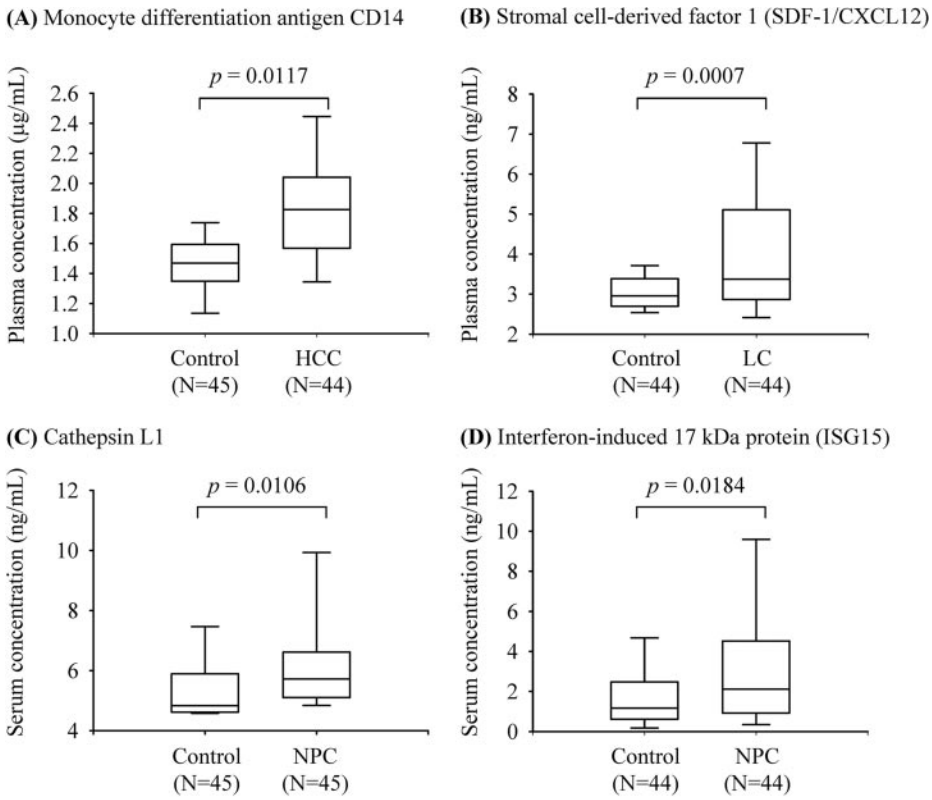

FIG. 6. **Validation of CD14, SDF-1, cathepsin L1, and ISG15 in serum/plasma samples.** The plasma levels of CD14 (*A*) and SDF-1 (*B*) in healthy controls (*Control*), liver cancer patients (*HCC*), and lung cancer patients (*LC*) were measured by sandwich ELISA. The serum levels of cathepsin L1 (*C*) and ISG15 (*D*) in healthy controls (*Control*) and NPC patients (*NPC*) were detected by sandwich ELISA. Data are presented as the upper and lower quartiles and range (*box*), the median value (*horizontal line*), and the middle 90% distribution (*dashed line*).

pivotal roles in tumor progression, invasion, metastasis, and/or angiogenesis by regulating cell-to-cell and cell-to-extracellular matrix interactions. More importantly, these secreted proteins are likely to enter bodily fluids and could therefore be measured using non-invasive diagnostic tests. Thus, the analysis of cancer cell secretomes derived *in vitro* may help identify potential serum tumor biomarkers (58, 59). Although the secretomes of cell lines derived from breast, ovarian, prostate, pancreatic, and lung cancers have been profiled individually (21–24, 28–30, 32, 51), no studies have compared the secretomes of cell lines from various cancer types or developed in-depth profiles of these proteins. We previously examined cancer cell secretomes using SDS-PAGE and MALDI-TOF MS (25). Now, the current study examines the secretomes of 23 cancer cell lines using the GeLC-MS/MS approach. We have generated, for the first time, a data set consisting of 31,180 protein identities, corresponding to 4,584 non-redundant proteins, with an approximate average of 1,300 proteins from each cell line and an error rate less than 1% (Table I and supplemental Table 1). We used this data set to compare the secretomes of cell lines from various cancer types, which were generated and analyzed using the same experimental conditions. Our analysis revealed numerous proteins that are commonly or selectively secreted by cell lines derived from different cancer types. Therefore, this valuable reference data set may facilitate the discovery of pan-cancer biomarkers and cancer type-specific biomarkers using a secretome-based strategy.

We and other groups have performed extensive studies to identify cancer-derived, body fluid-accessible marker candidates in conditioned media from various cancer cell lines. However, it has become apparent that not all proteins found in cancer cell secretomes are useful tumor-associated markers. Thus, researchers need a way to determine which candidates should be further validated as useful body fluid-accessible markers. Theoretically, the most likely candidates are proteins that are released by cancer cells and are overexpressed at a high frequency in tumor tissues. This notion is supported by recent immunohistochemical studies showing that numerous proteins are secreted by cancer cell lines and are overexpressed in cancerous tissues and that the serum and plasma levels of these proteins are indeed elevated in cancer patients (20, 23, 25–27, 31). These proteins include PAI-1 and Mac-2BP in patients with NPC (20), cathepsin D in patients with lung cancer (23), Mac-2BP and CRMP-2 (collapsin response mediator protein-2) in patients with CRC (25, 26), Mac-2BP in patients with oral cancer (27), and ALCAM, CD44, IL1R2, MIF, and TARC in patients with Hodgkin lymphoma (31). Studies that explore the tissue expression of proteins secreted by cell lines of different cancer types may therefore allow for the efficient prioritization of targets for subsequent validation.

The HPA is the first publicly available database containing information about protein expression in standardized normal human tissues, cancers, and *in vitro* cultured cell lines (60, 61). Much of these data have been analyzed via tissue mi-

croarrays (62), and the individual images have been annotated by certified pathologists. We searched the HPA database for cancer cell-secreted/released proteins of interest using an arbitrary selection criteria (*i.e.* proteins expressed in more than 50% of the tumor tissue sections examined) and thereby performed an *in silico* validation of the expression of hundreds of target proteins in various human cancers. Ultimately, we generated a list of ~470 serological cancer biomarker candidates from 11 cancer types for further validation (Table V and supplemental Table 7). In the present study, we confirmed the significantly elevated plasma levels of two such candidates (*i.e.* CD14 and SDF-1/CXCL12) in HCC and lung cancer patients, respectively (Fig. 6). The CD14 protein, a glycosylphosphatidylinositol-anchored glycoprotein of 50–55 kDa, was constitutively expressed on the surface of myeloid cells and acts as a pattern recognition receptor that plays an important role in innate immunity. A second soluble form of CD14 (sCD14) lacking the glycosylphosphatidylinositol tail was abundant in serum (63, 64). In addition to myeloid cells, recent studies have shown that CD14 is also expressed by many non-myeloid cells (65), including the hepatoma cell line Hep G2 (66, 67). Although many studies have examined the role of CD14 in infection- or immunity-related diseases, little is known about the possible significance of this protein in the development of cancer. To our knowledge, only one previous study reported higher preoperative serum levels of sCD14 in patients with epithelial ovarian cancer than in patients with benign ovarian disease (68). The SDF-1/CXCL12 protein is a member of the chemokine family that acts as a ligand for the CXCR4 receptor and plays multiple roles in tumor pathogenesis (69, 70). Although SDF-1/CXCL12 is overexpressed in numerous cancers, few studies have investigated SDF-1/CXCL12 levels in blood samples obtained from cancer patients (71–73), and the clinical significance of SDF-1/CXCL2 blood levels in most cancers is largely unknown. Our integrative analysis of cancer cell secretomes and the HPA reveals, for the first time, that CD14 and SDF-1/CXCL12 are potential plasma makers for HCC and lung cancer, respectively.

In addition to the 469 candidates selected from 11 cancer types, the present study also highlighted ~80 protein candidates as pan-cancer serological marker candidates. The expression of these marker candidates in specimens from nine cancer types has been validated in the HPA (supplemental Table 8). These candidates are involved in many biological processes, including metabolic processes (mainly the glycolytic enzymes), cell motility (cytoskeleton-related regulatory proteins), protein folding (molecular chaperones), proteolytic systems (proteosome and proteases), and protein synthesis. It has long been recognized that these biological processes are dysregulated in many cancers as is the expression of proteins and enzymes involved in these processes (74). However, few studies have systemically determined whether these proteins can be secreted by different types of cancer cells and whether these proteins are potentially useful serological markers for cancer. We addressed the former question and found that more than 170 proteins were released by all 23 cancer cell lines in serum-free conditions. It is possible that these proteins were detected in all cell lines because they are simply more abundant in the conditioned media. This notion is supported by our findings that most, if not all, of the 170 proteins were identified on the basis of multiple peptides and have significantly higher emPAI values than do proteins that were only detected in some cell lines (Table III and supplemental Tables 1 and 8). Another important question is whether proteins that are released by multiple cell lines and are highly expressed in most cancer types are, in fact, suitable serological pan-cancer marker candidates that should be further validated. Some of the target proteins on our list have been previously described as potential serological markers for various cancers. For example, elevated serum or plasma levels of galectin-3-binding protein (*i.e.* Mac-2BP) (75) have been reported in six cancer types, including breast cancer, HCC, lymphoma, NPC, CRC, and oral cancer (20, 26, 27, 76–78). Similarly, higher serum or plasma levels of cathepsin D have been detected in nine cancer types, including breast cancer, HCC, HNC, prostate cancer, glioma, CRC, stomach cancer, pancreatic cancer, and lung cancer (23, 79–85).

One of major challenges in the fields of tumor marker discovery and cancer biology is the formation of biological hypotheses about numerous marker candidates and the design of effective follow-up experiments (49). We evaluated our short list of secreted regulatory proteins for NPC using emPAI-based, label-free quantification and hierarchical clustering analyses in an effort to put our secretome data into a biological context (Fig. 4 and supplemental Table 9). It should be noted that the three NPC cell lines examined in this study originated from distinct NPC types. Specifically, NPC-TW02 and NPC-TW04 were derived from a keratinizing carcinoma and undifferentiated carcinoma, respectively (86), whereas NPC-BM1 was derived from a bone marrow biopsy of a patient with nonkeratinizing NPC (87). However, the three NPC cell lines could be clustered together with the proteins listed in supplemental Table 8, suggesting that these proteins and pathways may play an important role in NPC initiation or progression. We performed an additional pathway analysis by integrating our secretome data into a cellular signaling context. This analysis suggested that cell adhesion/migration and immune system regulation are among the most differentially regulated biological processes in NPC as compared with other cancers (Fig. 5 and supplemental Fig. 4). Metastasis has occurred in 7% of NPC patients by the time of initial diagnosis, and over 20% of patients with NPC develop metastasis after treatment (88, 89). In addition, immune suppression and evasion via the inactivation of tumor-infiltrating lymphocytes and imbalances in regulatory and effector T cells have been proposed in NPC patients (90, 91). We selected two targets for validation (*i.e.* cathepsin L1 and ISG15) that are known to be involved in the regulation of the immune system (Fig. 5*B*).

Cathepsin L1 (also known as cathepsin L, which is distinct from cathepsin L2 and cathepsin V) is a lysosomal cysteine protease that can degrade the components of extracellular matrices and basement membranes (92). This protease is overexpressed in a variety of cancer tissues (93). Cathepsin L1 is often overexpressed in metastatic cervical lymph node samples from patients with NPC, which correlates with lymph node metastasis and distant metastasis (53). The second target for validation, ISG15 (*i.e.* an interferon-stimulated gene also known as ubiquitin cross-reactive protein), plays a critical role in the interferon-mediated immune response against antiviral infection (94, 95). ISG15 was recently identified as a novel tumor marker candidate in bladder, breast, and oral cancers (96–98). However, we are the first to examine the serum levels of cathepsin L1 and ISG15 in patients with NPC, and our results show that the levels of these two proteins are higher in patients with NPC than in healthy controls. Taken together, these observations suggest that an emPAI-based, label-free quantification and hierarchical clustering analyses of multiple cancer cell secretomes, in conjunction with biological pathway analyses, are an effective strategy for discovering dysregulated pathway-based serological marker candidates in cancers such as NPC.

To date, ~8,800 antibodies have been applied against the human proteome to examine the expression of corresponding proteins in the HPA. There are still many human proteins whose expression in cancer tissues has not been systematically examined via immunohistochemical analyses and therefore could not be analyzed using the methods described here. Expression of these proteins in cancerous *versus* noncancerous tissues may be alternatively evaluated via the analysis of numerous cDNA microarray data sets available in the public domain, and the results could then be integrated with the cancer cell secretome data set to identify potential serological marker candidates. The feasibility of this notion is supported by our recent identification of Mac-2BP as a CRC plasma biomarker based on its apparent secretion by CRC cell lines and elevated transcriptional levels in a public array-based analysis of CRC tissues (26). In addition, we performed an in-house cDNA microarray analysis to demonstrate that the mRNA levels of cystatin A, manganese-superoxide dismutase, and MMP2 were higher in NPC tissues than in adjacent non-tumor tissues. We furthermore showed that these proteins were released by NPC cell lines and proposed that they serve as a potential serum biomarker panel for NPC (99). As immunohistochemical staining signals can vary with the use of different antibodies, our findings suggest that the potential serological markers identified using the strategy described here might complement the list of potential markers derived from the combined analysis of cancer cell secretomes and cancer tissue transcriptomes.

In conclusion, we have performed an in-depth comparative analysis of the secretomes of 23 cancer cell lines and have integrated our data with the HPA to generate a list of potential body fluid-accessible cancer biomarker candidates. The validation of potential cancer biomarkers requires a large cohort of well defined, high quality clinical specimens, a process that slows the discovery of clinically useful biomarkers (54, 55). Therefore, efficient strategies for narrowing down the list of proteins that are dysregulated in cancers would greatly reduce the costs of manpower, reagents, and precious clinical specimens. The potential cancer biomarkers described here could complement or serve as a useful alternative to previously constructed data sets (4, 57) for the more rapid validation of clinically useful biomarkers.

Supplementary Materials and Methods

Production of Recombinant Prosaposin and Antibodies against Prosaposin

The open reading frame of prosaposin C-terminal fragment (amino acid residue 301-525) was obtained from NPC-TW02 cells by polymerase chain reaction (PCR) using a sense primer, 5'-CGGGGTACCCCCATTAAGAAGCACGAGGT-3', and an antisense primer, 5'-CCGCTCGAGCTAGTTCCACACATGGCGTT-3', designed to introduce *Kpn*I and *Xho*I restriction sites at the 5' and 3' ends, respectively. The prosaposin gene fragment was ligated into the pGEM-T easy vector (Promega Corporation, Madison, WI, USA), and subcloned into the prokaryotic expression vector, pET-30a(+) (Novagen, Madison, WI, USA.). For production of His-tagged fusion protein, the construct was transformed into BL21 (DE3) cells (Novagen) and the recombinant protein was expressed by induction with 1 mM isopropyl-β-D-thiogalasctopyranoside (IPTG) at 37°C for 3 hr. The His-tagged fusion protein was purified by Ni^{2+}-NTA resin (GE Healthcare UK), according to the manufacturer's instructions. For generation of antibodies against prosaposin, rabbits were immunized with the prosaposin C-terminal fragment as described previously (1). Briefly, the rabbits were injected subcutaneously with 750 μg of purified proteins in 1.0 ml of PBS emulsified with an equal volume of complete Freund's adjuvant (Sigma, St. Louis, MO, USA). After 4 weeks, a booster dose of 750 μg of fusion protein emulsified in incomplete Freund's adjuvant (Sigma) was given. The methods used for sera collection and affinity purification of the antibody were as detailed in our previous report (2).

Production of Recombinant ISG15 and Antibodies against ISG15

The open reading frame of ISG15 was obtained from NPC-TW04 cells by PCR using a sense primer, 5'-GGATCCGGCTGGGACCTG-3', and an antisense primer, 5'-AAGCTTTTAGCTCCGCCCGCC-3', designed to introduce *Bam*HI and *Hin*dIII restriction sites at the 5' and 3' ends, respectively. The ISG15 gene fragment was ligated into the pGEM-T easy vector (Promega), and subcloned into the prokaryotic expression vector, pQE30 (Qiagen, Chatsworth, CA, USA). For production of His-tagged ISG15 protein, the pQE30-ISG15 construct was transformed into BL21 (DE3) cells (Novagen) and the

recombinant protein was expressed by induction with 0.5 mM IPTG for 3 hr, at 37°C. The His-tagged protein was purified by Ni^{2+}-NTA resin (GE Healthcare UK), according to the manufacturer's instructions. For generation of rabbit antibodies against ISG15, New Zealand White rabbits were immunized with His-tagged ISG15 protein as described previously (1). Briefly, the rabbits were injected subcutaneously with 500 μg of purified ISG15 in 1.0 ml of PBS emulsified with an equal volume of complete Freund's adjuvant (Sigma). After 4 weeks, a booster dose of 500 μg of ISG15 emulsified in incomplete Freund's adjuvant (Sigma) was given. The methods used for sera collection and affinity purification of the antibody were as detailed in our previous report (2)

ELISA of ISG15

To measure the serum ISG15 levels, white polystyrene 96-well plates (Corning, NY) were coated overnight at 4°C with the rabbit anti-ISG15 antibodies (3 μg/ml in PBS, 100 μl/well). The plates were then washed with PBS and blocked with 200 μl of BSA (1% in PBS; Sigma) at 37°C for 1 h. Recombinant ISG15 was used as the calibration standard. Serum samples (20 μl serum diluted in 30 μl 1% BSA/PBS) were added and incubated at 37°C for 2 h. After washing, biotin-conjugated anti-ISG15 antibodies (2.5 μg/ml in PBS, 100 μl/well) were applied. After 2 h, 100 μl of alkaline phosphatase-conjugated streptavidin (Santa Cruz Biotechnology) diluted 2000-fold in PBS was added. After 1 h, the substrate 4-methylumbelliferyl phosphate (100 μM, 100 μl/well; Molecular Probes, Eugene, OR) was added, and fluorescence was measured with the SpectraMax M5 reader ($\lambda_{excitation}$: 355 nm, $\lambda_{emission}$: 460 nm; Molecular Devices, Sunnyvale, CA).

The following is the instruction for interpretation of protein and peptide information in Supplementary Table 1.

Information of identified proteins is provided as follows:

1. Accession No.: accession number of the identified protein in IPI human sequence database v3.26.
2. Description: the name of identified protein in IPI human sequence database v3.26.
3. Gene symbol: A unique abbreviation of a gene name formally assigned by the HUGO

Gene Nomenclature Committee.

4. ProteinProphet: the protein probability scores calculated by ProteinProphet program.
5. emPAI: the values of Exponentially Modified Protein Abundance Index (emPAI) calculated on the basis of protein coverage by the peptide matches in a database search result.
6. SignalP: the signal peptide probability scores calculated by Hidden Markov models of SignalP program.
7. SecretomeP: the NN-scores calculated by SecretomeP program, which has been used to predict non-classical secretion.
8. TMHMM: “Yes” and “No” indicate proteins that are predicted as proteins with and without transmembrane helices, respectively.
9. No. of peptide identified: the number of identified peptides assigned to the protein.
10. Sequence coverage: the percentage obtained from the number of amino acid residues spanned by the assigned peptides divided by the number of amino acid residues of the full length sequence.
11. Identified peptide: the sequences of identified peptides assigned to the proteins.

Information of identified peptides assigned to the proteins is provided as follows:

1. PeptideProphet: the peptide probability scores calculated by PeptideProphet program that aids in the assignment of peptide MS spectrum.
2. SEQUEST scores XCorr, ΔCn, and RSp: the values of Xcorr, ΔCn, and RSp generated in Database Searching by SEQUEST algorithm.
3. ions: the observed numbers of fragmentation peaks/the expected numbers of fragmentation peaks.
4. Charge (+): the charge states of the identified peptides (precursor ions).
5. *m/z*: the experimental *m/z* values of the identified peptides (precursor ions).
6. Measured MH+: experimental m/z transformed to a relative molecular mass.
7. Calculated MH+: Calculated relative molecular mass of the matched peptide.
8. Mass diff. (Da): the value of measured peptide mass minus calculated peptide mass.
9. ppm: the ppm values of differences between the experimental and calculated masses.
10. Missing cleavages: number of missed enzyme cleavage sites.
11. pI: the expected pI values of identified peptides.

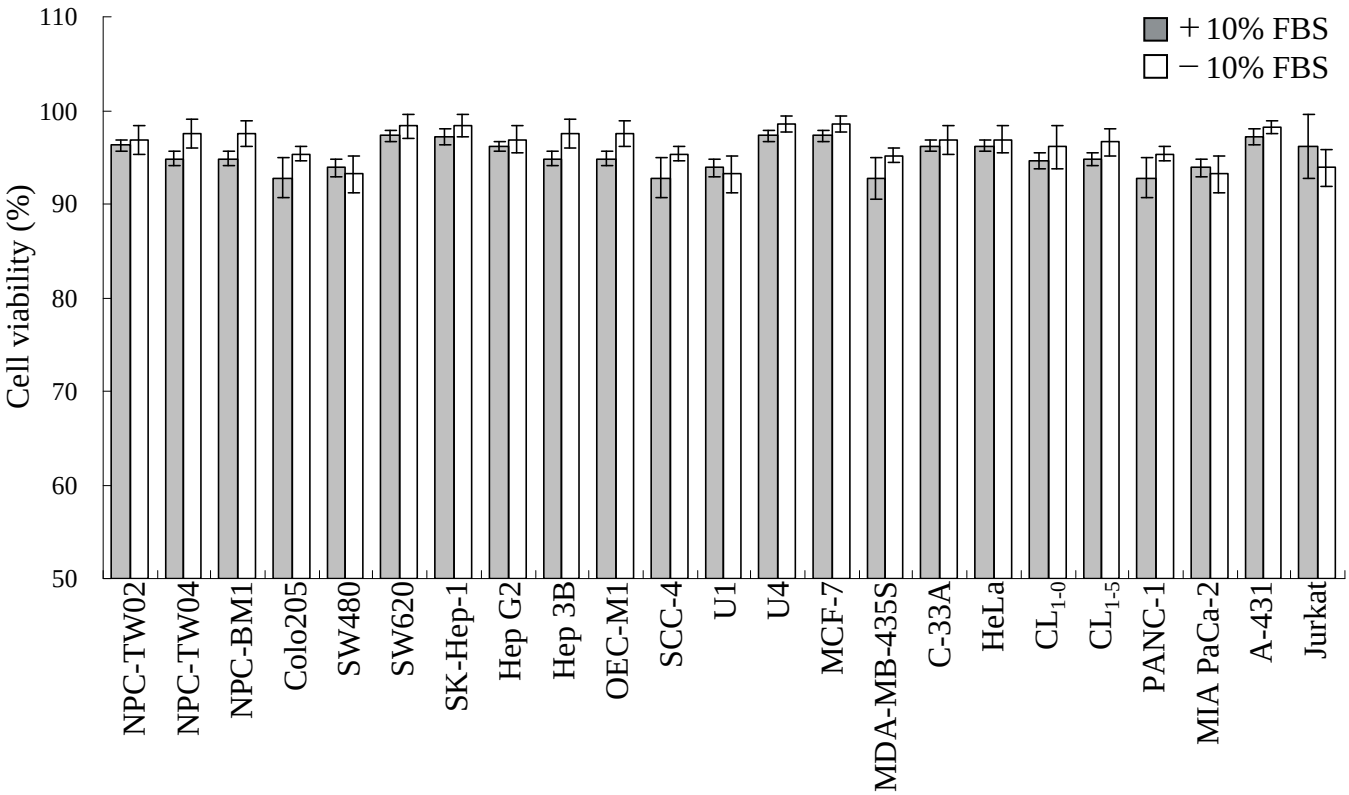
Instruction for Supplementary Table 7

The following is the instruction for interpretation of Human Protein Atlas information in Supplementary Table 7.

1. Cancer type: the types of human cancers

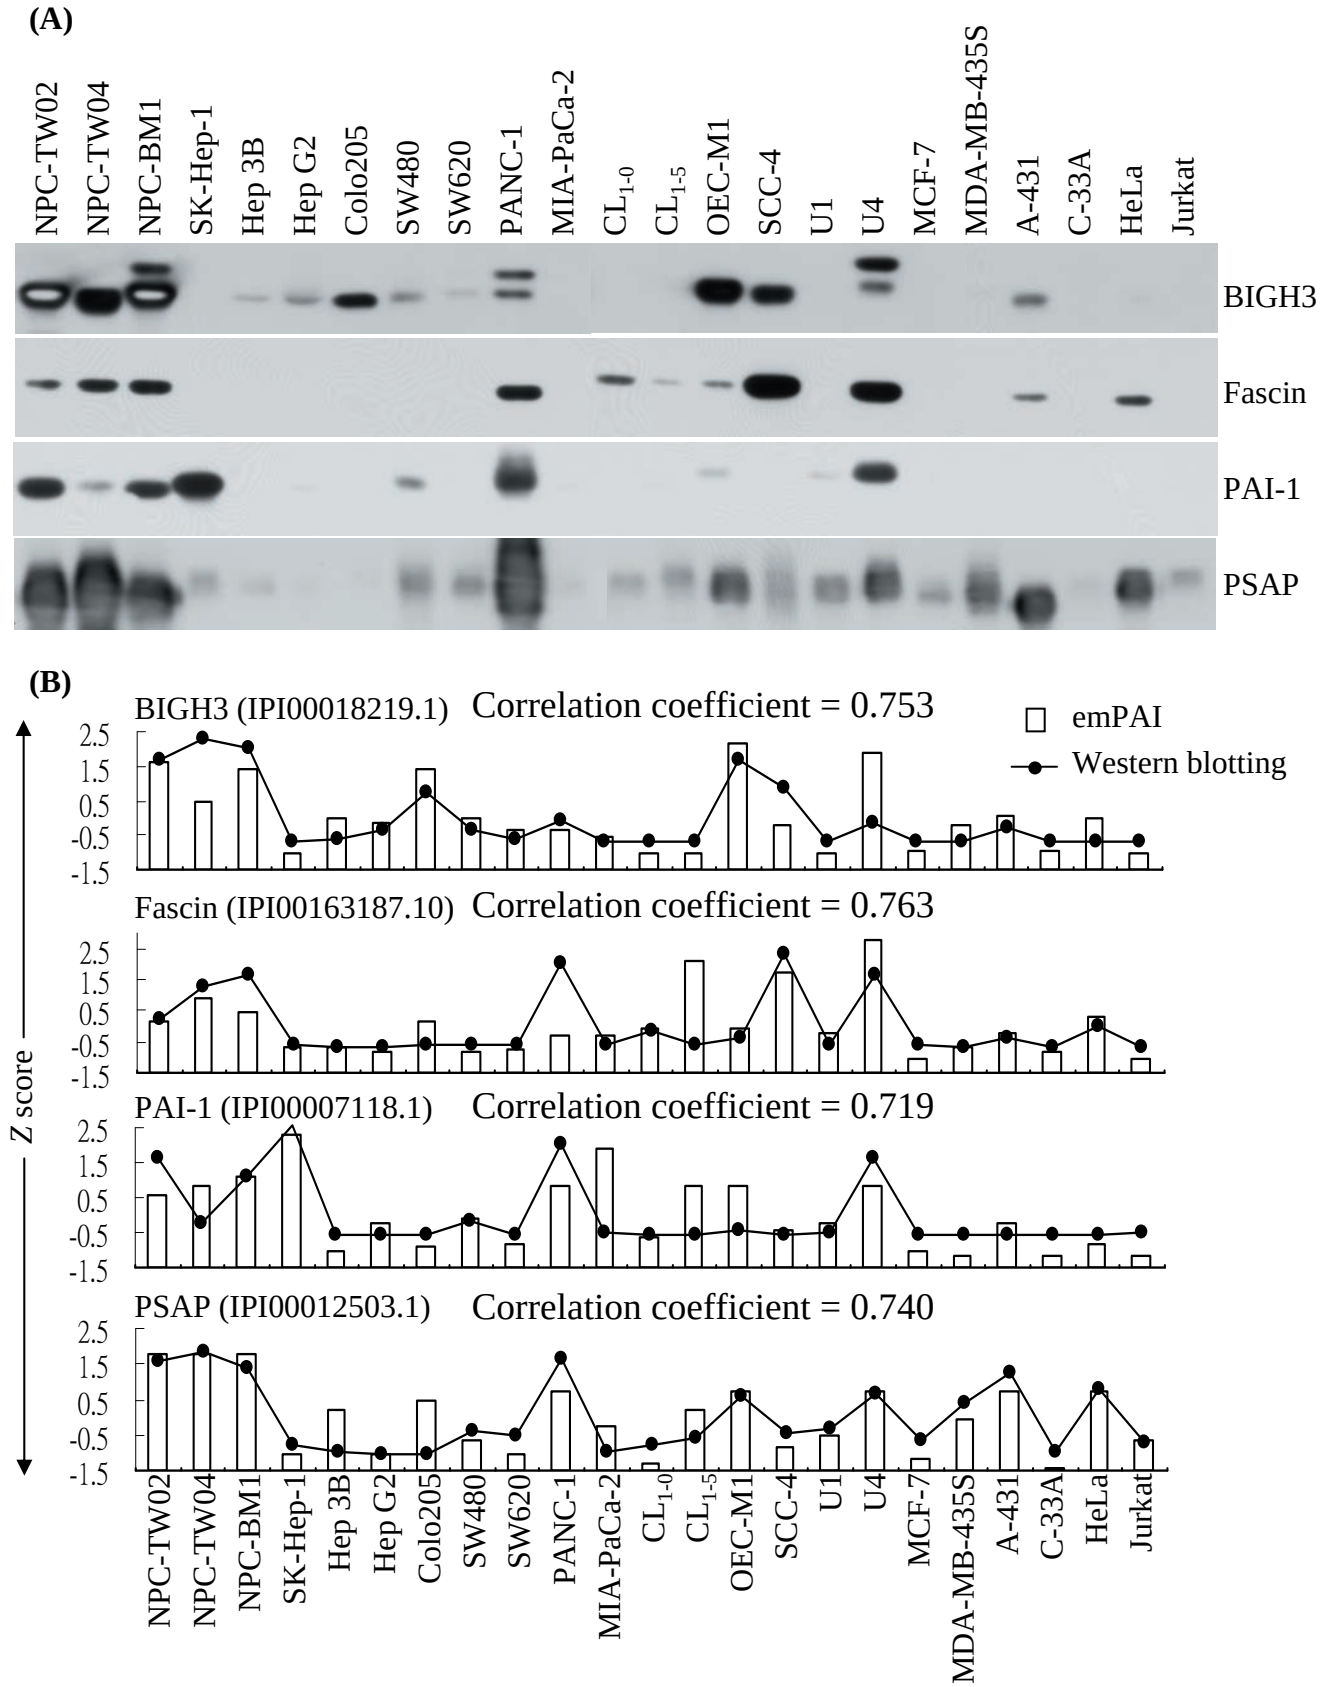
2. Accession No.: IPI protein accession number (v3.26) of the proteins that are identified in one cancer types.
3. Description: the names of the proteins that are identified in one cancer types.
4. Gene symbol: A unique abbreviation of a gene name formally assigned by the HUGO Gene Nomenclature Committee.
5. HPA antibody: the antibody ID in Human Protein Atlas database.
6. IHC staining in HPA: Strong: the numbers of IHC results with strong intensity; Moderate: the numbers of IHC results with moderate intensity; Weak: the numbers of IHC results with weak intensity; Negative: the numbers of IHC results with negative staining; Positive rate (%): the rates of IHC results with positive staining.

Instruction for Supplementary Table 8



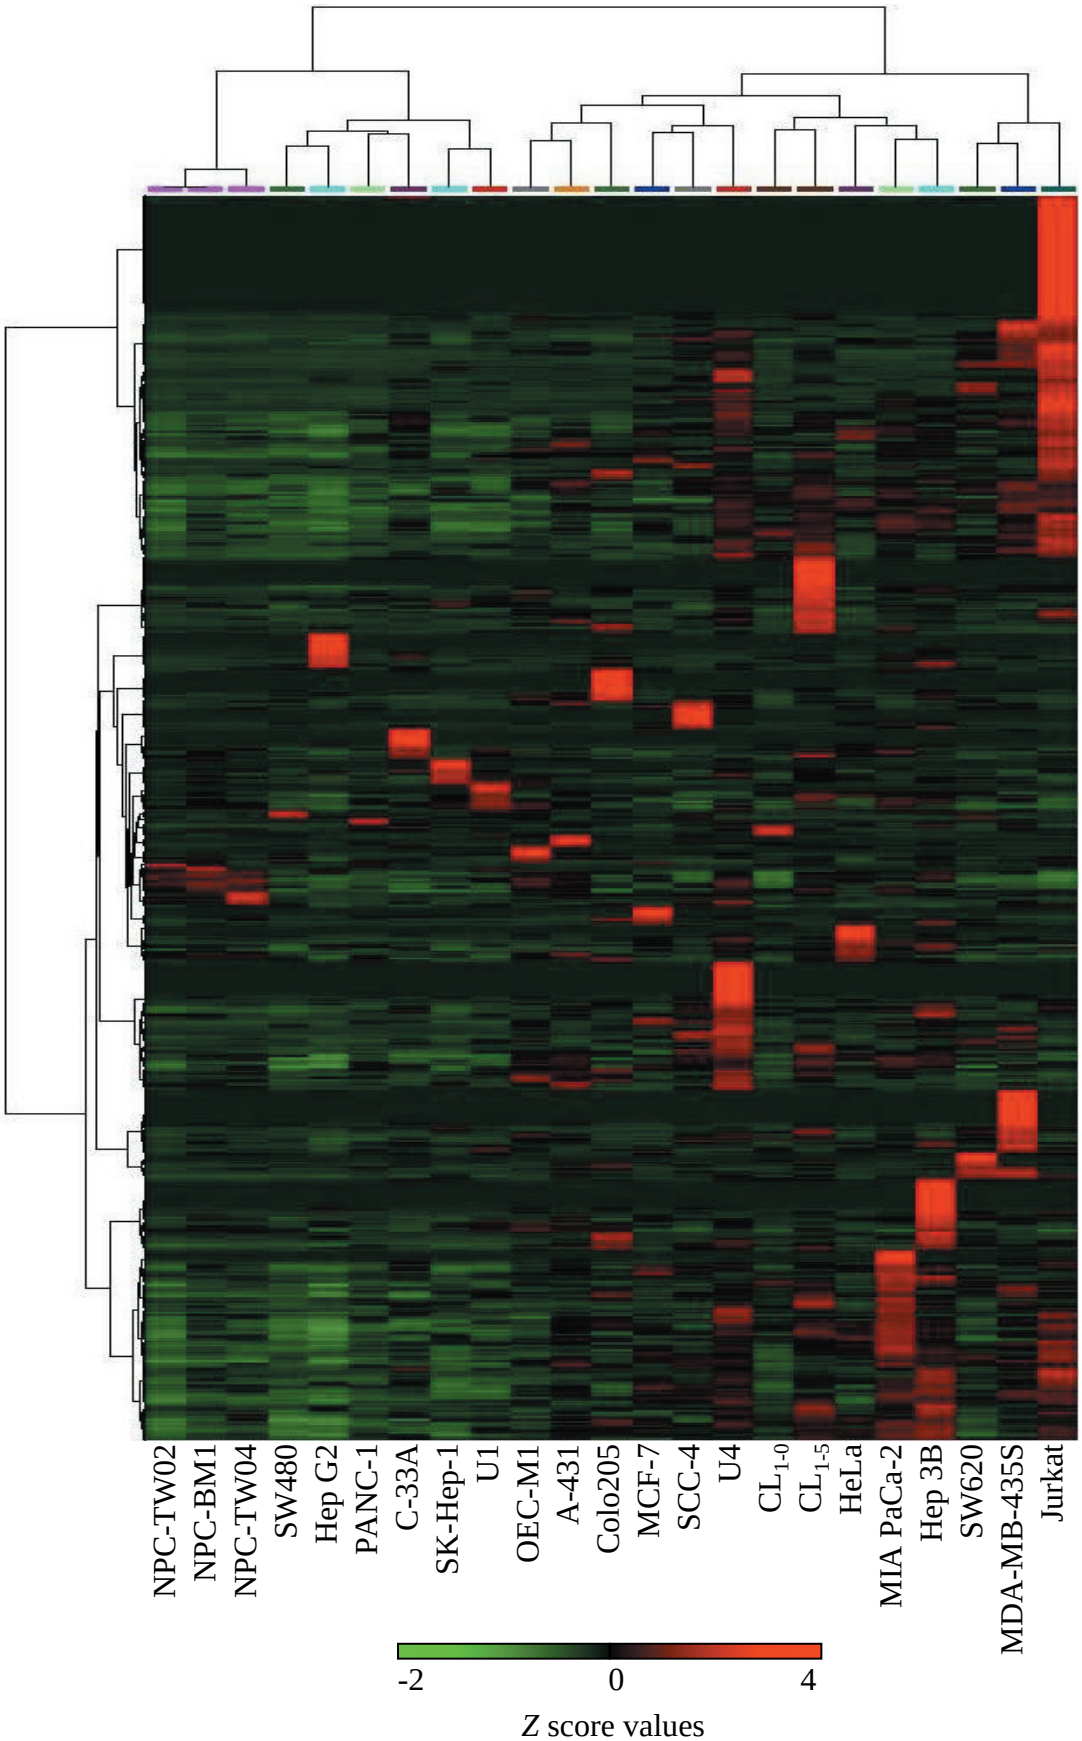
The following is the instruction for interpretation of Human Protein Atlas information in Supplementary Table 8.

1. Accession No.: IPI protein accession number (v3.26) of the proteins that are identified in all the cancer cell lines examined.
2. Description: the names of the proteins that are identified in all the cancer cell lines examined.
3. Gene symbol: A unique abbreviation of a gene name formally assigned by the HUGO Gene Nomenclature Committee.
4. HPA antibody: the antibody ID in Human Protein Atlas database.
5. IHC results in HPA: the number of IHC positive staining/the number of total IHC staining/intensity in the corresponding normal tissues.

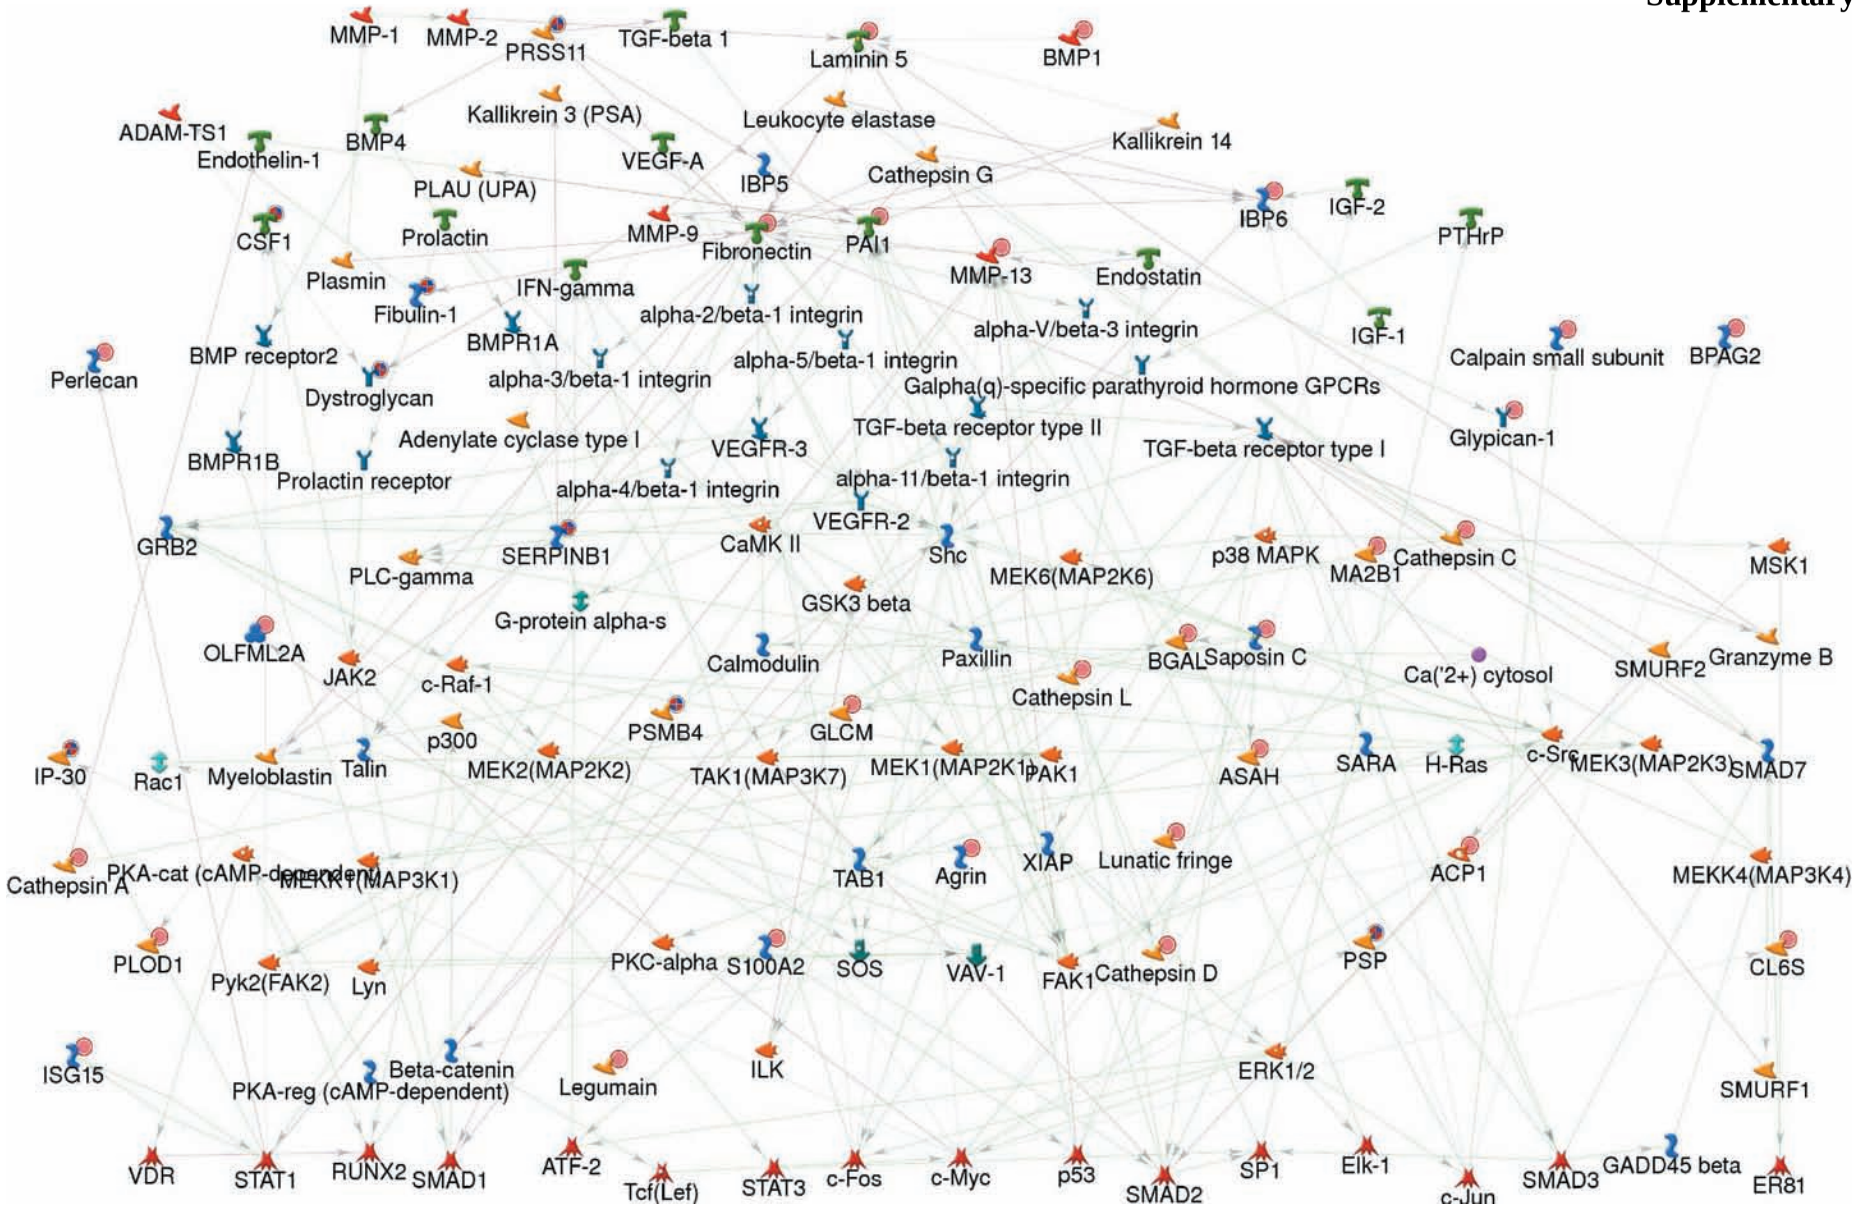


Instruction for Supplementary Table 9

The following is the instruction for interpretation of information in Supplementary Table 9.



1. Accession No.: IPI protein accession number (v3.26) of the proteins with the most different features for sorting NPC cell line from other cancer types.
2. Gene symbol: A unique abbreviation of a gene name formally assigned by the HUGO Gene Nomenclature Committee.
3. Description: the names of the identified proteins with the most different features for sorting NPC cell line from other cancer types.
4. *Z* score normalized protein abundance: the *Z* scores of the proteins with the most different features for sorting NPC cell line from other cancer types.



Supplementary Figure 1. Viability of cancer cell lines grown in complete or serum-free medium for 24 h. Cells were seeded in complete medium for 24 h, then grown in complete medium or serum-free medium for an additional 24 h. Cells suspended in media and attached on plates were collected separately, and the numbers of viable and dead cells in each fraction were determined using the trypan blue dye exclusion assay. The percentage of cell viability was expressed as the ratio of total viable cells to the sum of total viable and dead cells.

Supplementary Figure 2. Correlation between the *Z* score-normalized emPAI values and the Western blot signal intensities of four proteins detected in conditioned media from 23 cancer cell lines. (A) Proteins (20 μg) from the conditioned media were analyzed via Western blotting with antibodies specific to BIGH3, fascin, PAI-1, and PSAP. (B) The relative densities of protein bands in panel B were quantitatively analyzed using ImageQuant software, and normalized according to *Z* scores. The *Z* score-normalized emPAI values (bar) were correlated with the *Z* scores from the Western blotting analysis (solid line).

Supplementary Figure 3. Hierarchical clustering of cancer cell lines, according to the relative abundance of proteins identified in the conditioned media. The emPAI values of all identified proteins were transformed to *Z* scores and analyzed via unsupervised hierarchical classification. Columns represent cell lines and rows denote proteins. The heat map scale of *Z* scores ranges from -2 (green) to 4 (red), with a midpoint of 0 (black).

Supplementary Figure 4. Biological network analysis of NPC-related proteins. The 79 proteins shown in Fig. 4B were uploaded to the MetaCore mapping tool. A network was generated using the 'shortest path' algorithm to map interaction between the proteins. Nodes represent proteins, and lines between the nodes indicate direct protein-protein interactions. The concentric circles denote 36 of the 79 proteins included in this analysis.

Annotation Summary - IHC

Most normal tissues and malignant tissues were negative. Leydig cells in testis, glandular cells in epididymis, adrenal cortex, macrophages and a subset of inflammatory cells infiltrating in normal as well as malignancies displayed strong cytoplasmic positivity.

help for this page

Annotation Summary - IHC

A majority of the normal and malignant cells showed negative cells or weakly stained cytoplasm and/or nucleus. Bone marrow poietic cells showed strong nuclear positivity. Moderate positivity was observed for example in adrenal cortical cells, thyroid, renal tubules and cells in seminiferus ducts. Malignant melanomas and renal cancers displayed moderate cytoplasmic immunoreactivity in a majority of cases while malignant lymphomas displayed occasional strong positivity.
